Overview of Binder Collection Lounge

For this final project, we plan to develop a mobile application for trading card fans that combines three key features: an e-commerce store for buying different types of cards, a deck builder for organizing and testing builds, and a section that displays nearby event listings so users can find tournaments, competitions, and community meetups. Our target audience includes people who are passionate about trading card games such as Magic: The Gathering, Pokémon, and sports cards, among others. The app will provide users with an easy-to-use store where they can browse card listings, search for items they want, purchase cards online with confidence, build strong decks, display their collections online, and find events that's right for them.

Scope and Objectives

The scope for this project is to build a mobile trading card application that offers users a combination of features not commonly found in other apps. The app will include an e-commerce section where users can browse and purchase collectible cards across multiple categories such as Magic: The Gathering, Pokémon, and sports cards. It will also provide a deck-building area for users to organize, create, and save their decks, as well as showcase their collections. In addition, the app will have a section for viewing nearby events based on location, helping users participate more easily in the trading card game community.

The primary objective of this application is to make it easier for trading card collectors to shop for cards online, organize their collection through deck building, showcase achievements, and stay connected to local events. The application aims to deliver a smooth, user-friendly experience for both beginners and experienced collectors.

Feature Specifications

1. Users who are selling cards on the app will be able to create listings on the app available for sale and have the price of the card that is being sold displayed inside of the listing.
2. Sellers will be able to upload an image of the card they are trying to sell, and attach it to the listing they create
3. The seller will be able to make different listings for each card that they are looking to sell, and each listing will have its own unique price.
4. A feature that allows the user to create, manage, and edit decks inside the application for Trading Card Games (TCG).
5. There will be multiple sections inside of our application, including a place for sellers to sell and post their cards, a place for buyers to shop online, and a place to view your binder
6. A place where users can add different cards to their collection and keep them all organized in one place. There will be a way to upload an image of the card, and a way to display a title under the card, showing off what the user has!
7. There will be a feature that will show nearby events, stores, and card shows going on in the area when the user inputs a zip code.
8. There will be a search bar where users can go and find the cards that they are looking for, by searching under different criteria to find the card they want (e.g., name, set, team, type).

Non-Functional Requirements

1. The user will be required to create an account to log in to the application. This enhances the security and safety of our application.
2. Our interface will be easy to read and navigate, regardless of how long the user has been a collector of trading cards.

3. When you are clicking on different elements inside of our app, the response time of the application will be quick and seamless.
4. Our application will be able to be used on an IOS or Android device.

Glossary

- TCG (Trading Card Game)- Games where players use collectible cards to play the game. (e.g., Magic the Gathering, One Piece, Pokémon)
- E-Commerce Store- The section of the app where users can look at, and purchase cards online
- Deck Builder- A tool that allows the user to create, manage, and organize the card decks that they have.
- Card Listing- A page where details of the card for sale is displayed. (e.g. name, condition, price, type of card).
- Search Bar – A place where users can type information in, and that will help find the card the collector is looking for, based on the information that was inputted.
- Nearby Events- Competitions, Events, Tournaments, and Card Shows that are displayed based on the user's inputted location.
- User Account – A profile that allows users to save their decks, collections, and make purchases.
- Checkout – The place of purchase, where users confirm their items, payment details, and shipping address.

Assumptions

- The user has internet access and a mobile device capable of running IOS or Android functions.
- User will allow location access or enter a location to find nearby events.
- Payment processing will be handled using a third-party payment provider (e.g., card payments using an external service).
- Event listings will come from a data source (e.g., partner feeds. event provider integration).
- This app will support at least the three main card categories covered in the project, Magic the Gathering, Pokémon, and Sports cards.
- Users can create, manage, and edit decks using the rules/constraints defined in each game (where applicable).

Code and Challenges

For the code, we built it in Expo Dev, since it was a mobile app and then we moved it over to github per the assignment's requirement.

Expo Snack: <https://snack.expo.dev/@deimos4763/bindercollectionlounge>

Amador: Some challenges I personally faced during this project were mostly the development of the code. We did have a big idea which took a week for us to build the code. We did run into many issues, so there was alot of debugging. However, after taking turns debugging, we were able to get the app to work the way we intended at least for the mock model.

Garrett: Some challenges that I faced were with the cards, and the names of variables. The cards were confusing because there being 3 different types of cards, each with thousands if not millions of different cards printed. We needed a system of naming that would be efficient for any

number. There were also so many different variables, style names, and function names that got confusing. One other big challenge was that I was programming tired, and had a few spelling errors, which led to more bugs than we already had.

User Manual

When the user first opens the app, they should be ideally entering a login screen. This mock app does not have it, but later in time it will be added. The user will create an account which they will then enter the shop screen. This is where the user can check out what cards are for sale that includes cards for Magic: The Gathering, Pokémon, sports cards, etc. They can add to their cart and search for any cards they are interested in purchasing. The next screen is the deck screen where users are able to build different playing decks. They are able to name whatever they like, pick up the game the deck is for, and users are able to randomly add cards and later they will be able to look for cards they would want in their decks and search for in the shop. Next, is the binder screen where users will be able to add cards they have collected digitally. The events screens, the user just enters a zipcode and it will show the events happening around that area.
